class edge:

```
1. public class edge: IComparable<edge>
```

A class which holds each edge weight, start point and end point.

```
1. public double distance = 0;  
2. public int[] points = new int[2];
```

and implements function CompareTo to enable sorting according to the distances

```
1. public int CompareTo(edge other) => other.distance.CompareTo(this.distance) * -1;
```

class ImageOperations:

A class to hold all functions to perform distinct colors extracting, MST constructing, clustering, pallet generating, DisplayImage and Quantizing the image

Functions description and complexity:

OpenImage:

```
1. public static RGBPixel[,] OpenImage(string ImagePath, ref int[, ] mapper, ref List<RGBPixel> colorSet)
```

parameters:

ImagePath => which takes the path of the image to open.

Mapper => As reference 3D Boolean array to map every color to a position according to red, green, blue values to create a simple set which adds the color if mapper[red, green, blue] = false which means the color is not present in the list “colorSet” and changes the value to true to avoid adding the color again to the list.

colorSet => As reference List which initially holds no colors and after the execution of the function it holds all distinct colors from the image to pass it to the other functions later.

Complexity: while reading the image it checks for every color “ $O(N^2)$ ” in this snippet

```
1. for (y = 0; y < Height; y++) //O(N)  
2.     for (x = 0; x < Width; x++) //O(N)
```

if it is present in the mapper or not “ $O(1)$ ” in this snippet

```
1. if (colorsBoolArray[Buffer[y, x].red, Buffer[y, x].green, Buffer[y, x].blue] == false) // O(1)  
2. {  
3.     colorsBoolArray[Buffer[y, x].red, Buffer[y, x].green, Buffer[y, x].blue] = true; //O(1)  
4.     colorSet.Add(Buffer[y, x]); //O(1)  
5.     graph.Add(new List<int>());  
6. }
```

Which means over all “ $O(N^2)$ ” complexity for extracting the distinct colors.

CalculateMST:

```
1. public static List<edge> CalculateMST(int numberOfDistinctColors, List<RGBPixel> colorSet)
```

parameters:

numberOfDistinctColors: an integer value which holds the number of distinct colors.

colorSet: the list which holds the distinct colors itself.

Attributes:

```
1.  bool[] partnersOfTheTree = new bool[numberOfDistinctColors];
2.  int least = 0, localLeast = 0;
3.  double min, dist;
4.  edge tmp;
5.  List<edge> MST = new List<edge>();
6.
```

partnersOfTheTree: a Boolean array which maps every color from colorSet depending on the index of each color to show if the color is already in the tree or not

least, localLeast: an integer value which holds the index of the starting point of distance calculations which is considered the point which optimal edge found (initially set the first color in index 0)

min: a double value to hold the minimum edge weight.

dist: a double value to hold the current edge weight to compare it to min and add it to the MST(if selected).

tmp: a pointer to hold an edge from the MST to avoid re calculating in every access.

MST: a list to hold the selected edges for creating the minimum spanning tree and to be returned as a result for the function.

Complexity:

The looping the separated to 2 phases

phase 1:

Looping from 0 to all other vertices and calculating the distances for every edges

```
1.  dist = Math.Sqrt(Math.Pow(colorSet[localLeast].red - colorSet[j].red, 2) +
2.  Math.Pow(colorSet[localLeast].green - colorSet[j].green, 2) +
3.  Math.Pow(colorSet[localLeast].blue - colorSet[j].blue, 2));
```

Then creates the initial MST which holds all edges from color 0 to all other colors ... which makes the first feasible solution and not the optimal solution (No cycle but not the best cost) and has a size of (V-1) then chooses the least distance to point to the next edge to loop from (like Dijkstra)

```
1.  int k = 1;
2.      // loops from 0 to all other vertices
3.      while (k < numberOfDistinctColors)//O(N)
4.      {
5.          // calculating the distance
6.          byte red1 = colorSet[localLeast].red;//O(1)
7.          byte green1 = colorSet[localLeast].green;//O(1)
8.          byte blue1 = colorSet[localLeast].blue;//O(1)
9.          byte red2 = colorSet[k].red;//O(1)
10.         byte green2 = colorSet[k].green;//O(1)
11.         byte blue2 = colorSet[k].blue;//O(1)
12.         double red = (red1 - red2) * (red1 - red2);//O(1)
13.         double green = (green1 - green2) * (green1 - green2);//O(1)
14.         double blue = (blue1 - blue2) * (blue1 - blue2);//O(1)
15.         dist = Math.Sqrt(red + green + blue);//O(1)
16.         // adding the edge to the initial MST
17.         MST.Add(new edge(dist, 0, k));//O(1)
18.         graph[localLeast].Add(k);//O(1)
19.         graph[k].Add(localLeast);//O(1)
20.         // checks if it is the minimum edge to start from its end
```

```

21.         if (dist < min)//O(1)
22.         {
23.             // change the minimum
24.             min = dist;//O(1)
25.             // save the index of the next start over
26.             least = k;//O(1)
27.         }
28.         k++;
29.     }

```

Which is done in $O(N)$ as it loops only for all other vertices.

Phase 2:

Looping from all vertices except of the first one to every other vertex to compare with the initial MST to check if better way(distance) to reach a specific vertex and replace it.

It is done in $O(1)$ as comparing with the pervious best wat is done with indexing the MST as it is kind of sorted and the order is not changing in the entire code.

```

1.  k = 1;
2.      // looping from every vertex exept of 0 to the others
3.      while (k < numberOfDistinctColors)//O(N)
4.      {
5.          //reset the min for every vertex
6.          min = 99999;
7.          //set the startPoint as optiml way found
8.          partnersOfTheTree[least] = true;
9.          // reserve the start point index to prevent fomr modifications
10.         localLeast = least;
11.         // check the distance to all others from the current start point
12.         for (int j = 1; j < numberOfDistinctColors; j++)//O(D)
13.         {
14.             // exclude the optimal points if found
15.             if (partnersOfTheTree[j] == false)//O(D)
16.             {
17.                 // calculating the distance
18.                 byte red1 = colorSet[localLeast].red;//O(1)
19.                 byte green1 = colorSet[localLeast].green;//O(1)
20.                 byte blue1 = colorSet[localLeast].blue;//O(1)
21.                 byte red2 = colorSet[j].red;//O(1)
22.                 byte green2 = colorSet[j].green;//O(1)
23.                 byte blue2 = colorSet[j].blue;//O(1)
24.                 double red = (red1 - red2) * (red1 - red2);//O(1)
25.                 double green = (green1 - green2) * (green1 - green2);//O(1)
26.                 double blue = (blue1 - blue2) * (blue1 - blue2);//O(1)
27.                 dist = Math.Sqrt(red + green + blue);//O(1)
28.                 // hold the edge to reduce access time
29.                 tmp = MST[j];//O(1)
30.                 //check if it is a better way to this vertex
31.                 if (dist < tmp.distance)//O(1)
32.                 {
33.                     graph[j].Remove(MST[j].points[0]);//O(N)
34.                     graph[MST[j].points[0]].Remove(j);//O(N)
35.                     //replace the distance
36.                     MST[j].distance = dist;//O(1)
37.                     //replace the starting index
38.                     MST[j].points[0] = localLeast;//O(1)
39.                     graph[j].Add(MST[j].points[0]);//O(1)
40.                     graph[MST[j].points[0]].Add(j);//O(1)
41.                 }
42.                 //check if it is the best edge in the tree to set the next start point
43.                 if (tmp.distance < min)//O(1)
44.                 {
45.                     //change the min
46.                     min = tmp.distance;//O(1)
47.                     // reserve the index
48.                     least = tmp.points[1]);//O(1)
49.                 }

```

```

50.     }
51.     k++;
52.     }

```

Which means over all “ $O(D^2)$ ” complexity for calculating the distance from every vertex to all other vertices and extracting the MST edges.

clustering:

```

1. public static List<List<int>> clustering (int numberOfDistinctColors, List<edge> MST, int k)

```

parameters:

numberOfDistinctColors => an integer value which holds the number of distinct colors.

MST => the list that holds the edges which creates the minimum spanning tree.

K => the number of desired clusters for this image

```

1. List<List<int>> clusters = new List<List<int>>();
2. int[] indexer = new int[numberOfDistinctColors];
3. int cluster = 1, unClusterd = numberOfDistinctColors, numberOfClusters = 0, p1, p2, I1, I2;
4. edge tmp;

```

clusters => list which holds a list of clusters that is extracted from the function and to be returned.

Indexer => an integer array to map every color from colorSet to it is cluster Number

Cluster => defines the number of the current cluster to be added and initially set to 1

unClusterd => the number of not yet clustered vertices initially set to numberOfDistinctColors and decrements

numberOfClusters => the number of clustered vertices initially set to 0 and increments.

p1, p2, I1, I2 => pointers to point for every wanted index from indexer or color to avoid re calculating

tmp: a pointer to hold an edge from the MST to avoid re calculating in every access.

Complexity:

first step is to sort the MST List to access the least distance ascendingly

```

1. MST.Sort(); // O(NlogN)

```

Clustering is done by accessing the MST from the least distance ascendingly and combining every to points for an edge according to some conditions in 2 phases

First phase: has 4 conditions

First condition is if the 2 vertices are clustered to different clusters, then we will combine the 2 clusters

```

1. if (I1 != 0 && I2 != 0 && I1 != I2) // O(1)
2. {
3.     int keep = I2;
4.     clusters[keep - 1].ForEach(l => indexer[l] = I1); // O(D)
5.     clusters[I1 - 1].AddRange(clusters[keep - 1]); // O(D)
6.     clusters[keep - 1].Clear(); // O(1)
7.     numberOfClusters--; // O(1)
8. }

```

The second and third conditions are the same to check if only one from those points is clustered then we add the not clustered one to the other's cluster

```
1.  else if (I1 != 0)
2.  {
3.      indexer[p2] = I1;
4.      clusters[I1 - 1].Add(p2);
5.      unClusterd--;
6.
7.  }
8.  else if (I2 != 0)
9.  {
10.     indexer[p1] = I2;
11.     clusters[I2 - 1].Add(p1);
12.     unClusterd--;
13. }
```

The fourth condition is if the 2 points are not clustered yet then we add the 2 points to a new cluster

```
1.  else
2.  {
3.      List<int> tempCluster = new List<int>();
4.      tempCluster.Add(tmp.points[0]);
5.      tempCluster.Add(tmp.points[1]);
6.      clusters.Add(tempCluster);
7.      indexer[p1] = cluster;
8.      indexer[p2] = cluster;
9.      cluster++;
10.     numberOfClusters++;
11.     unClusterd -= 2;
12. }
```

The second phase has 3 conditions and is started by the condition:

```
1.  if (numberOfClusters + unClusterd == k)
```

and the 2 main conditions is checking for the remaining edges if any 1 of 2 points is not clustered yet

```
1.  if (I1 == 0)//O(1)
2.  {
3.      List<int> tempCluster = new List<int>();//O(1)
4.      tempCluster.Add(p1); //O(1)
5.      clusters.Add(tempCluster); //O(1)
6.      indexer[p1] = cluster; //O(1)
7.      cluster++; //O(1)
8.      numberOfClusters++; //O(1)
9.      unClusterd--; //O(1)
10. }
11. if (I2 == 0)
12. {
13.     List<int> tempCluster = new List<int>();//O(1)
14.     tempCluster.Add(p2); //O(1)
15.     clusters.Add(tempCluster); //O(1)
16.     indexer[p2] = cluster; //O(1)
17.     cluster++; //O(1)
18.     numberOfClusters++; //O(1)
19.     unClusterd--; //O(1)
20. }
21. continue;
22.
```

and the third condition is if all vertices are clustered then break the loop

```
1. if (unClusterd == 0) break;
```

Which means over all “ $O(K \cdot D)$ ” complexity for clustering the colors

Clustering with bonus:

First we calculate the mean

```
1. int MSTCOUNT = MST.Count() - 1; //O(1)
2. double MEAN = MST_SUM / MSTCOUNT; //O(1)
```

then standard deviation

```
1. double stdSUM = 0; //O(1)
2. int STDcount = MSTCOUNT - 1; //O(1)
3. // calculate the standard deviation
4. for (int i = 0; i < MSTCOUNT; i++) //O(E) bounds loop
5.     stdSUM += (MST[i].distance - MEAN) * (MST[i].distance - MEAN);
6. stdSUM /= STDcount;
7. stdSUM = Math.Sqrt(stdSUM);
```

our stopping condition is when the reduction is exceedingly small value

```
1. while (Math.Abs(stdSUM - stdSUM_loop) >= 0.0001 || h == 0) //O(K) bounds loop // to check if stopping
```

which means we need to check all MST edges to check which makes the most reduction as a naive solution or in more efficiently we can say that the best value to exclude is the most far away from the mean

```
1. if (Math.Abs(MST[r].distance - MEAN) >= MST[h].distance - MEAN) // decide which makes more reduction
```

in a sorted array this means the first or the last value

then we break the chosen edge the same steps if it is the first or the last

```
1. // breaking the edge
2. graph[MST[r].points[0]].Remove(MST[r].points[1]); //O(N)
3. graph[MST[r].points[1]].Remove(MST[r].points[0]); //O(N)
```

then we recalculate the mean by excluding the chosen edge weight

```
1. //calculate new mean
2. MEAN = MEAN * (STDcount + 1);
3. MEAN = MEAN - MST[r].distance;
4. MEAN = MEAN / STDcount;
```

Then skipping the edge and loop again to calculate the standard deviation

```
1. r--; // skipping this edge
2. //calculate new standard deviation
3. for (int i = h; i < r; i++) //O(E) bounds loop
4.     stdSUM_loop += (MST[i].distance - MEAN) * (MST[i].distance - MEAN);
5. stdSUM_loop /= STDcount;
6. stdSUM_loop = Math.Sqrt(stdSUM_loop);
```

we added a condition to handle mathematical exception to stop the loop

```
1. if (STDcount == 0) break; // handle error
```

after ending the last loop then we have broken our MST to K subtrees

the next step is to BFS on it to create the clusters

```
1. for (int i = 0; i < graph.Count; i++)//O(D)
2.     if (partnersOfTheTree[i] == false)
3.     {
4.         clusters.Add(new List<int>());//O(1)
5.         q.Enqueue(i);//O(1)
```

we add every point to get its direct neighbors to create the cluster

```
1. while (q.Count != 0)//O(D)
2.     {
3.
4.         // temp to hold peek to reduce time then Dequeue
5.         var tmpQ = q.Dequeue();
6.         // adding all direct connactions
7.         for (int j = 0; j < graph[tmpQ].Count; j++)//O(D)
8.             if (partnersOfTheTree[graph[tmpQ][j]] == false)//O(1) //to avoid retake
9.                 q.Enqueue(graph[tmpQ][j]);//O(1)
10.        partnersOfTheTree[tmpQ] = true;//O(1)// mark as taken
11.        clusters[cluster_counter].Add(tmpQ);//O(1) // add to cluster
12.
13.    }
```

The overall complexity is $O(K+D)$

generatePallete:

```
1. public static List<RGBPixel> generatePallete(List<List<int>> clusters, List<RGBPixel> colorSet, ref int[,.] mapper)
```

parameters:

clusters: the list of clusters that holds all vertices with all clusters

colorSet: the list of distinct colors

mapper: an integer array thar maps between every color and it's cluster representative color

attributes:

```
1. List<RGBPixel> palletaa = new List<RGBPixel>();
2. int clusterCounter = 0, count = clusters.Count;
3. double red = 0, green = 0, blue = 0;
4. int numberOfClusterElements
5. RGBPixel current;
```

palletaa: is the list that holds every cluster representative color

clusterCounter: an integer to hold clusters ID to assign to the mapper

current : a pointer to hold the color to add to pallet later.

Complexity:

we loop on clusters to get the list of specific clusters

```
1. for (int i = 0; i < count; i++) //O(K)
```

then we loop on those colors in this cluster to calculate avg for every red , green , blue

```
1. foreach (var j in clusters[i]) //O(D)
2. {
3.     red = red + colorSet[j].red; // O(1)
4.     green = green + colorSet[j].green; // O(1)
5.     blue = blue + colorSet[j].blue; // O(1)
6.     mapper[colorSet[j].red, colorSet[j].green, colorSet[j].blue] = clusterCounter; // O(1)
7. }
```

Then we assign this color to pallet and assign the same id to every color in this cluster to help with mapping every color to its cluster representative color

```
1. current.red = (byte)Math.Ceiling(red / numberOfClusterElements);
2. current.green = (byte)Math.Ceiling(green / numberOfClusterElements);
3. current.blue = (byte)Math.Ceiling(blue / numberOfClusterElements);
4. palletaa.Add(current);
5. clusterCounter++;
```

as the number of loops will be bounded by the number of distinct colors then the overall “O (D)” complexity for generating pallet

Quantize:

```
1. public static RGBPixel[,] Quantize(RGBPixel[,] ImageMatrix, List<RGBPixel> p, int[, ] mapper)
```

ImageMatrix: the image which we want to perform quantization on

P: the color pallet

Mapper: the array that maps every color to its representative color

Complexity:

We loop on the image matrix to get every pixel and we check it on the mapper to get its cluster id and check it in the pallet list to change the color to its representative color

```
1. for (int i = 0; i < Height; i++)// O(N)
2. for (int j = 0; j < Width; j++)// O(N)
3. {
4.     RGBPixel quantized = new RGBPixel(); // O(1)
5.     quantized = p[mapper[ImageMatrix[i, j].red, ImageMatrix[i, j].green, ImageMatrix[i, j].blue]]; //O(1)
6.     Filtered[i, j].red = quantized.red; // O(1)
7.     Filtered[i, j].green = quantized.green; // O(1)
8.     Filtered[i, j].blue = quantized.blue; // O(1)
9. }
10.
```

Then we return the quantized image

Which means over all “O (N^2)” complexity for mapping each color to its representative color
